## New Foreword

On October 1, 2001 Axiom was withdrawn from the market and ended life as a commercial product. On September 3, 2002 Axiom was released under the Modified BSD license, including this document. On August 27, 2003 Axiom was released as free and open source software available for download from the Free Software Foundation's website, Savannah.

Work on Axiom has had the generous support of the Center for Algorithms and Interactive Scientific Computation (CAISS) at City College of New York. Special thanks go to Dr. Gilbert Baumslag for his support of the long term goal.

The online version of this documentation is roughly 1000 pages. In order to make printed versions we've broken it up into three volumes. The first volume is tutorial in nature. The second volume is for programmers. The third volume is reference material. We've also added a fourth volume for developers. All of these changes represent an experiment in print-on-demand delivery of documentation. Time will tell whether the experiment succeeded.

Axiom has been in existence for over thirty years. It is estimated to contain about three hundred man-years of research and has, as of September 3, 2003, 143 people listed in the credits. All of these people have contributed directly or indirectly to making Axiom available. Axiom is being passed to the next generation. I'm looking forward to future milestones.

With that in mind I've introduced the theme of the "30 year horizon". We must invent the tools that support the Computational Mathematician working 30 years from now. How will research be done when every bit of mathematical knowledge is online and instantly available? What happens when we scale Axiom by a factor of 100, giving us 1.1 million domains? How can we integrate theory with code? How will we integrate theorems and proofs of the mathematics with space-time complexity proofs and running code? What visualization tools are needed? How do we support the conceptual structures and semantics of mathematics in effective ways? How do we support results from the sciences? How do we teach the next generation to be effective Computational Mathematicians?

The "30 year horizon" is much nearer than it appears.

Tim Daly

## 0.1 Makefile

This book is actually a literate program[2] and contains executable source code. In particular, the Makefile for this book is part of the source of the book and is included below. Axiom uses the “noweb” literate programming system by Norman Ramsey[6].

# Chapter 1

## Overview

The Spad language is a mathematically oriented language intended for writing computational mathematics. It derives its logical structure from abstract algebra. It features ideas that are still not available in general purpose programming languages, such as selecting overloaded procedures based on the return type as well as the types of the arguments.

The Spad language is heavily influenced by Barbara Liskov's work. It features encapsulation (aka objects), inheritance, and overloading. It has categories which are defined by the exports. Categories are parameterized functors that take arguments which define their behavior.

More details on the language and its high level concepts is available in the Programmers Guide, Volume 3.

The Spad compiler accepts the Spad language and generates a set of files used by the interpreter, detailed in Volume 5.

The compiler does not produce stand-alone executable code. It assumes that it will run inside the interpreter and that the code it generates will be loaded into the interpreter.

Some of the routines are common to both the compiler and the interpreter. Where this happens we have favored the interpreter volume (Volume 5) as the official source location. In each case we will make reference to that volume and the code in it. Thus, the compiler volume should be considered as an extension of the interpreter document.

This volume will go into painful detail of every aspect of compiling Spad code. We will start by defining the input to, and output from the compiler so we know what we are trying to achieve.

Next we will look at the top level data structures used by the compiler. Unfortunately, the compiler uses a large number of “global variables” to pass information and alter control flow. Some of these are used by many routines and some of these are very local to a small subset or a recursion. We will cover the minor ones as they arise.

Next we examine the Pratt parser idea and the Led and Nud concepts, which is used to drive the low level parsing.

Following that we journey deep into the code, trying our best not to get lost in the details. The code is introduced based on “motivation” rather than in strict execution order or related concept order. We do this to try to make the compiler a “readable novel” rather than a mud-march through the code. The goal is to keep the reader’s interest while trying to be exact. Sometimes this will require detours to discuss subtopics.

“Motivating” a piece of software is a not-very-well established form of narrative writing so we assume your forgiveness if we get it wrong. Worse yet, some of the pieces of the system are “legacy”, in that they are no longer used and should be removed. Other parts of the system may have very weak descriptions because we simply do not understand them either. Since this is a living document and the code for the system is actually the code you are reading we will expand parts as we go.

## 1.1 The Input

```
)abbrev domain EQ Equation
--FOR THE BENEFIT OF LIBAXO GENERATION

## 1.2 The Output, the EQ.nrlib directory

The Spad compiler generates several files in a directory named after the input abbreviation. The input file contains an abbreviation line:

```
)abbrev domain EQ Equation
```

for each category, domain, or package. The abbreviation line has 3 parts.

- one of “category”, “domain”, or “package”
- the abbreviation for this domain (8 Uppercase Characters maximum)
- the name of this domain

Since the abbreviation for the Equation domain is EQ, the compiler will put all of its output into a subdirectory called “EQ.nrlib”. The “nrlib” is a port of a very old VMLisp file format, simulated with directories.

For the EQ input file, the compiler will create the following output files, each of which we will explain in detail below.

```
/research/test/int/algebra/EQ.nrlib:

## 1.4 The code.o file

The Spad compiler translates the Spad language into Common Lisp. It eventually invokes the Common Lisp “compile-file” command to output files in binary. Depending on the lisp system this filename can vary (e.g “code.fasl”). The details of how these are used depends on the Common Lisp in use.

By default, Axiom uses Gnu Common Lisp (GCL), which generates “.o” files.

## 1.7 The index.kaf file

Each constructor (e.g. EQ) had one library directory (e.g. EQ.nrlib). This directory contained a random access file called the index.kaf file. These files contain runtime information such as the operationAlist and the ConstructorModemap. At system build time we merge all of these .nrlib/index.kaf files into one database, INTERP.daase. Requests to get information from this database are cached so that multiple references do not cause additional disk i/o.

Before getting into the contents, we need to understand the format of an index.kaf file. The kaf file is a random access file, originally used as a database. In the current system we make a pass to combine these files at build time to construct the various daase files.

This is just a file of lisp objects, one after another, in (read) format.

A kaf file starts with an integer, in this case, 35695. This integer gives the byte offset to the index. Due to the way the file is constructed, the index is at the end of the file. To read a kaf file, first read the integer, then seek to that location in the file, and do a (read). This will return the index, in this case:

```
(("slot1Info" 0 32444)
 ("documentation" 0 29640)
 ("ancestors" 0 28691)
 ("parents" 0 28077)
 ("abbreviation" 0 28074)
 ("predicates" 0 25442)
 ("attributes" 0 25304)
 ("signaturesAndLocals" 0 23933)
 ("superDomain" 0 NIL)
 ("operationAlist" 0 20053)
 ("modemaps" 0 17216)
 ("sourceFile" 0 17179)
 ("constructorCategory" 0 15220)
 ("constructorModemap" 0 13215)
 ("constructorKind" 0 13206)
 ("constructorForm" 0 13191)
 ("compilerInfo" 0 4433)
 ("loadTimeStuff" 0 20))
```

This is a list of triples. The first item in each triple is a string that is used as a lookup key (e.g. “operationAlist”). The second element is no longer used. The third element is the byte offset from the beginning of the file.

So to read the “operationAlist” from this file you would:

1. open the index.kaf file
2. (read) the integer
3. (seek) to the integer offset from the beginning of the file
4. (read) the index of triples
5. find the keyword (e.g. “operationAlist”) triple
6. select the third element, an integer
7. (seek) to the integer offset from the beginning of the file
8. (read) the “operationAlist”

Note that the information below has been reformatted to fit this document. In order to save space the index.kaf file does not use prettyprint since it is normally only read by machine.

### 1.7.1 The index offset byte

35695

### 1.7.2 The “loadTimeStuff”

# Chapter 2

## Compiler top level

### 2.1 Global Data Structures

### 2.2 Pratt Parsing

Parsing involves understanding the association of symbols and operators. Vaughn Pratt [8] poses the question “Given a substring AEB where A takes a right argument, B a left, and E is an expression, does E associate with A or B?”.

Floyd [9] associates a precedence with operators, storing them in a table, called “binding powers”. The expression E would associate with the argument position having the highest binding power. This leads to a large set of numbers, one for every situation.

Pratt assigns data types to “classes” and then creates a total order on the classes. He lists, in ascending order, Outcomes, Booleans, Graphs (trees, lists, etc), Strings, Algebraics (e.g. Integer, complex numbers, polynomials, real arrays) and references (e.g. the left hand side of assignments). Thus, Strings  $\downarrow$  References. The key restriction is “that the class of the type at any argument that might participate in an association problem not be less than the class of the data type of the result of the function taking that argument”.

For a less-than comparision (“ $<$ ”) the argument types are Algebraics but the result type is Boolean. Since Algebraics are greater than Boolean we can associate the Algebraics together and apply them as arguments to the Boolean.

In more detail, there an “association” is a function of 4 types:

- $a_A$  – The data type of the right argument
- $r_A$  – The return type of the right argument
- $a_B$  – The data type of the left argument
- $r_B$  – The return type of the left argument

Note that the return types might depend on the type of the expression E. If all 4 are of the same class then the association is to the left.

Using these ideas and given the restriction above, Pratt proves that every association problem has at most one solution consistant with the data types of the associated operators.

Pratt proves that there exists an assignment of integers to the argument positions of each token in the language such that the correct association, if any, is always in the direction of the argument position with the larger number, with ties being broken to the left.

To construct the proper numbers, first assign even integers to the data type classes. Then to each argument position assign an integer lying strictly (where possible) between the integers corresponding to the classes of the argument and result types.

For tokens like “and”, “or”, +, \*, and the Booleans and Algebraics can be subdivided into pseudo-classes so that

terms < factors < primaries

Then + is defined over terms, \* over factors, and over primaries with coercions allowed from primaries to factors to terms. To be consistent with Algol, the primaries should be a right associative class (e.g. xyz)

## 2.3 )compile

This is the implementation of the )compile command.

You use this command to invoke the new Axiom library compiler or the old Axiom system compiler. The )compile system command is actually a combination of Axiom processing and a call to the Aldor compiler. It is performing double-duty, acting as a front-end to both the Aldor compiler and the old Axiom system compiler. (The old Axiom system compiler was written in Lisp and was an integral part of the Axiom environment. The Aldor compiler is written in C and executed by the operating system when called from within Axiom.)

**User Level Required:** compiler

**Command Syntax:**

```
)compile
)compile fileName
)compile fileName.spad
)compile directory/fileName.spad
)compile fileName )old
)compile fileName )translate
)compile fileName )quiet
)compile fileName )noquiet
```

```
)compile fileName )moreargs
)compile fileName )onlyargs
)compile fileName )break
)compile fileName )nobreak
)compile fileName )library
)compile fileName )nolibrary
)compile fileName )vartrace
)compile fileName )constructor nameOrAbbrev
```

These command forms invoke the Aldor compiler.

```
)compile fileName.as
)compile directory/fileName.as
)compile fileName.ao
)compile directory/fileName.ao
)compile fileName.al
)compile directory/fileName.al
)compile fileName.lsp
)compile directory/fileName.lsp
)compile fileName )new
```

#### **Command Description:**

The first thing )compile does is look for a source code filename among its arguments. Thus

```
)compile mycode.spad
)compile /u/jones/mycode.spad
)compile mycode
```

all invoke )compiler on the file */u/jones/mycode.spad* if the current Axiom working directory is */u/jones*. (Recall that you can set the working directory via the )cd command. If you don't set it explicitly, it is the directory from which you started Axiom.)

If you omit the file extension, the command looks to see if you have specified the )new or )old option. If you have given one of these options, the corresponding compiler is used.

The command first looks in the standard system directories for files with extension *.as*, *.ao* and *.al* and then files with extension *.spad*. The first file found has the appropriate compiler invoked on it. If the command cannot find a matching file, an error message is displayed and the command terminates.

The first thing )compile does is look for a source code filename among its arguments. Thus

```
)compile mycode
)co mycode
)co mycode.spad
```

all invoke `)compiler` on the file `/u/jones/mycode.spad` if the current Axiom working directory is `/u/jones`. Recall that you can set the working directory via the `)cd` command. If you don't set it explicitly, it is the directory from which you started Axiom.

This is frequently all you need to compile your file.

This simple command:

1. Invokes the Spad compiler and produces Lisp output.
2. Calls the Lisp compiler if the compilation was successful.
3. Uses the `)library` command to tell Axiom about the contents of your compiled file and arrange to have those contents loaded on demand.

Should you not want the `)library` command automatically invoked, call `)compile` with the `)nolibrary` option. For example,

```
)compile mycode )nolibrary
```

By default, the `)library` system command *exposes* all domains and categories it processes. This means that the Axiom interpreter will consider those domains and categories when it is trying to resolve a reference to a function. Sometimes domains and categories should not be exposed. For example, a domain may just be used privately by another domain and may not be meant for top-level use. The `)library` command should still be used, though, so that the code will be loaded on demand. In this case, you should use the `)nolibrary` option on `)compile` and the `)noexpose` option in the `)library` command. For example,

```
)compile mycode )nolibrary
)library mycode )noexpose
```

Once you have established your own collection of compiled code, you may find it handy to use the `)dir` option on the `)library` command. This causes `)library` to process all compiled code in the specified directory. For example,

```
)library )dir /u/jones/quantum
```

You must give an explicit directory after `)dir`, even if you want all compiled code in the current working directory processed, e.g.

```
)library )dir .
```

### 2.3.1 Spad compiler

This command compiles files with file extension `.spad` with the Spad system compiler.

The `)translate` option is used to invoke a special version of the old system compiler that will translate a `.spad` file to a `.as` file. That is, the `.spad` file will be parsed and analyzed and a file using the new syntax will be created.

By default, the `.as` file is created in the same directory as the `.spad` file. If that directory is not writable, the current directory is used. If the current directory is not writable, an error message is given and the command terminates. Note that `)translate` implies the `)old` option so the file extension can safely be omitted. If `)translate` is given, all other options are ignored. Please be aware that the translation is not necessarily one hundred percent complete or correct. You should attempt to compile the output with the Aldor compiler and make any necessary corrections.

You can compile category, domain, and package constructors contained in files with file extension `.spad`. You can compile individual constructors or every constructor in a file.

The full filename is remembered between invocations of this command and `)edit` commands. The sequence of commands

```
)compile matrix.spad
)edit
)compile
```

will call the compiler, edit, and then call the compiler again on the file **matrix.spad**. If you do not specify a *directory*, the working current directory is searched for the file. If the file is not found, the standard system directories are searched.

If you do not give any options, all constructors within a file are compiled. Each constructor should have an `)abbreviation` command in the file in which it is defined. We suggest that you place the `)abbreviation` commands at the top of the file in the order in which the constructors are defined.

The `)library` option causes directories containing the compiled code for each constructor to be created in the working current directory. The name of such a directory consists of the constructor abbreviation and the `.nrlib` file extension. For example, the directory containing the compiled code for the **MATRIX** constructor is called **MATRIX.nrlib**. The `)nolibrary` option says that such files should not be created. The default is `)library`. Note that the semantics of `)library` and `)nolibrary` for the new Aldor compiler and for the old system compiler are completely different.

The `)vartrace` option causes the compiler to generate extra code for the constructor to support conditional tracing of variable assignments. Without this option, this code is suppressed and one cannot use the `)vars` option for the trace command.

The `)constructor` option is used to specify a particular constructor to compile. All other constructors in the file are ignored. The constructor name or abbreviation follows `)constructor`. Thus either

```
)compile matrix.spad )constructor RectangularMatrix
```

or

```
)compile matrix.spad )constructor RMATRIX
```

compiles the `RectangularMatrix` constructor defined in `matrix.spad`.

The `)break` and `)nobreak` options determine what the spad compiler does when it encounters an error. `)break` is the default and it indicates that processing should stop at the first error. The value of the `)set break` variable then controls what happens.

## 2.4 Operator Precedence Table Initialization

```
; PURPOSE: This file sets up properties which are used by the Boot lexical
; analyzer for bottom-up recognition of operators. Also certain
; other character-class definitions are included, as well as
; table accessing functions.
;
; ORGANIZATION: Each section is organized in terms of Creation and Access code.
;
;           1. Led and Nud Tables
;           2. GLIPH Table
;           3. RENAMETOK Table
;           4. GENERIC Table
;           5. Character syntax class predicates
```

### 2.4.1 LED and NUD Tables

```
; **** 1. LED and NUD Tables
;
; ** TABLE PURPOSE
;
; Led and Nud have to do with operators. An operator with a Led property takes
; an operand on its left (infix/suffix operator).
;
; An operator with a Nud takes no operand on its left (prefix/nilfix).
; Some have both (e.g. - ). This terminology is from the Pratt parser.
; The translator for Scratchpad II is a modification of the Pratt parser which
; branches to special handlers when it is most convenient and practical to
; do so (Pratt's scheme cannot handle local contexts very easily).
;
; Both LEDs and NUDs have right and left binding powers. This is meaningful
; for prefix and infix operators. These powers are stored as the values of
; the LED and NUD properties of an atom, if the atom has such a property.
; The format is:
;
;       <Operator Left-Binding-Power Right-Binding-Power <Special-Handler>>
```

```
; where the Special-Handler is the name of a function to be evaluated when that
; keyword is encountered.

; The default values of Left and Right Binding-Power are NIL. NIL is a
; legitimate value signifying no precedence. If the Special-Handler is NIL,
; this is just an ordinary operator (as opposed to a surfix operator like
; if-then-else).

;

; The Nud value gives the precedence when the operator is a prefix op.
; The Led value gives the precedence when the operator is an infix op.
; Each op has 2 priorities, left and right.
; If the right priority of the first is greater than or equal to the
; left priority of the second then collect the second operator into
; the right argument of the first operator.
```

### — LEDNUDTables —

—————

## 2.5 Gliph Table

Glyphs are symbol clumps. The gliph property of a symbol gives the tree describing the tokens which begin with that symbol. The token reader uses the gliph property to determine the longest token. Thus := is read as one token not as : followed by =.

— GLIPHTable —

```
(mapcar #'(lambda (x) (put (car x) 'gliph (cdr x)))
  '(
    ( \| (\))
    ( * (*))
    ( \( (<) (\|))
    ( + (- (>)))
    ( - (>))
    ( < (=) (<))
    ( ; ( / (\\")) ) breaks */xxx
    ( \\" (/))
    ( > (=) (>) (\())))
    ( = (= (>)) (>))
    ( \. (\..))
    ( ^ (=))
    ( \~ (=))
    ( \: (=) (-) (\:))))
```

—————

### 2.5.1 Rename Token Table

RENAMETOK defines alternate token strings which can be used for different keyboards which define equivalent tokens.

— RENAMETOKTable —

```
(mapcar
 #'(lambda (x) (put (car x) 'renametok (cadr x)) (makenewop x nil))
 '(((\| \[] ; (| |) means []
 (\| \) \[])
 (\(< \{)
 (>) \}))) ; (< >) means {}
```

---

### 2.5.2 Generic function table

GENERIC operators be suffixed by \$ qualifications in SPAD code. \$ is then followed by a domain label, such as I for Integer, which signifies which domain the operator refers to. For example +\$Integer is + for Integers.

— GENERICTable —

```
(mapcar #'(lambda (x) (put x 'generic 'true))
      '(- = * |rem| |mod| |quo| |div| / ** |exquo| + - < > <= >= ^= ))
```

---

## 2.6 Giant steps, Baby steps

We will walk through the compiler with the EQ.spad example using a Giant-steps, Baby-steps approach. That is, we will show the large scale (Giant) transformations at each stage of compilation and discuss the details (Baby) in subsequent chapters.

# Chapter 3

## The Parser

### 3.1 EQ.spad

We will explain the compilation function using the file `EQ.spad`. We trace the execution of the various functions to understand the actual call parameters and results returned. The `EQ.spad` file is:

```
)abbrev domain EQ Equation

      z
      '(cons , (car z) ,(newConstruct (cdr z)))))
```

---

### 3.3 preparse

The first large transformation of this input occurs in the function `preparse`. The `preparse` function reads the source file and breaks the input into a list of pairs. The first part of the pair is the line number of the input file and the second part of the pair is the actual source text as a string.

One feature that is the added semicolons at the end of the strings where the “pile” structure of the code has been converted to a semicolon delimited form.

#### 3.3.1 defvar \$index

---

— initvars —

```
(defvar $index 0 "File line number of most recently read line")
```

---

#### 3.3.2 defvar \$linelist

---

— initvars —

```
(defvar $linelist nil "Stack of prepared lines")
```

---

#### 3.3.3 defvar \$echolinestack

---

— initvars —

```
(defvar $echolinestack nil "Stack of lines to list")
```

---

### 3.3.4 defvar \$preparse-last-line

— initvars —

```
(defvar $preparse-last-line nil "Most recently read line")
```

---

## 3.4 Parsing routines

The **initialize-preparse** expects to be called before the **preparse** function. It initializes the state, in particular, it reads a single line from the input stream and stores it in **\$preparse-last-line**. The caller gives a stream and the **\$preparse-last-line** variable is initialized as:

```
2> (INITIALIZE-PREPARE #<input stream "/tmp/EQ.spad">)
<2 (INITIALIZE-PREPARE ")abbrev domain EQ Equation")
```

### 3.4.1 defun initialize-preparse

```
[get-a-line p638]
[$index p75]
[$linelist p75]
[$echolinestack p75]
[$preparse-last-line p76]
```

— defun initialize-preparse —

```
(defun initialize-preparse (strm)
  (setq $index 0)
  (setq $linelist nil)
  (setq $echolinestack nil)
  (setq $preparse-last-line (get-a-line strm)))
```

---

The **preparse** function returns a list of pairs of the form: ( (linenumber . linestring) .... (linenumber . linestring)) For instance, for the file **EQ.spad**, we get:

```

2> (PREPARSE #<input stream "/tmp/EQ.spad">)
3> (PREPARSE1 ("")abbrev domain EQ Equation")
4> (|doSystemCommand| "abbrev domain EQ Equation")
<4 (|doSystemCommand| NIL)

    (nconc lines '(" ")) (nconc locs '(nil)))
  lines)
```

---

### 3.4.5 defun add-parens-and-semis-to-line

The line to be worked on is (CAR SLINES). It's indentation is (CAR SLOCS). There is a notion of current indentation. Then:

- Add open paren to beginning of following line if following line's indentation is greater than current, and add close paren to end of last succeeding line with following line's indentation.
- Add semicolon to end of line if following line's indentation is the same.
- If the entire line consists of the single keyword then or else, leave it alone.”

```
[infixtok p555]
[drop p553]
[addclose p552]
[nonblankloc p555]
```

— defun add-parens-and-semis-to-line —

## 4.2 Indirect called parse routines

In the `parseTran` function there is the code:

```
((and (atom u) (setq fn (getl u '|parseTran|)))
  (funcall fn arg1))
```

The functions in this section are called through the symbol-plist of the symbol being parsed.  
The original list read:

and	parseAnd
@	parseAtSign
CATEGORY	parseCategory
::	parseCoerce
\:	parseColon
construct	parseConstruct
DEF	parseDEF
\$<=	parseDollarLessEqual
\$>	parseDollarGreaterThan
\$>=	parseDollarGreaterEqual
\$^=	parseDollarNotEqual
eqv	parseEquivalence
exit	parseExit
>	parseGreaterThan
>=	parseGreaterEqual
has	parseHas
IF	parseIf
implies	parseImplies
IN	parseIn
INBY	parseInBy
is	parseIs
isnt	parseIsnt
Join	parseJoin
leave	parseLeave
;control-H	parseLeftArrow
<=	parseLessEqual
LET	parseLET
LETD	parseLETD
MDEF	parseMDEF
~	parseNot
not	parseNot
^=	parseNotEqual
or	parseOr
pretend	parsePretend
return	parseReturn
SEGMENT	parseSegment

```

SEQ          parseSeq
;;control-V  parseUpArrow
VCONS       parseVCONS
where       parseWhere

```

#### 4.2.1 defplist parseAnd

## Chapter 5

# Compile Transformers

With some specific exceptions most compile transformers are invoked through the property list item “**special**”. When a specific keyword is encountered in a list form the `compExpression` function looks up the keyword on the property list and funcalls the handler function, passing the form, the mode, and the environment.

If a handler for the keyword is not found then the `compForm` function is called to attempt to compile the form.

### 5.0.86 defun compExpression

```
[getl p??]
[compForm p602]
[$insideExpressionIfTrue p??]

— defun compExpression —

(defun |compExpression| (form mode env)
  (let (|$insideExpressionIfTrue| fn)
    (declare (special |$insideExpressionIfTrue|))
    (setq |$insideExpressionIfTrue| t)
    (if (and (atom (car form)) (setq fn (getl (car form) 'special)))
        (funcall fn form mode env)
        (|compForm| form mode env))))
```

---

The functions in this section are called through the symbol-plist of the symbol being parsed. In general, each of these functions takes 3 arguments

1. the **form** which is specific to the function

2. the **mode** a —Join—, which is a set of categories and domains
3. the **env** which is a list of functions and their modemap

and the functions return modified versions of the three arguments suitable for further pro-

    "compileCases"                [color="#ECEA81"]
    "compileDocumentation"       [color="#ECEA81"]

    "compDefine" -> "compDefine1"
    "compDefine1" -> "compDefineCapsuleFunction"
    "compDefine1" -> "compDefWhereClause"
    "compDefine1" -> "compDefineAddSignature"
    "compDefine1" -> "compDefineCategory"
    "compDefine1" -> "compDefineFunctor"
    "compDefine1" -> "compInternalFunction"
    "compDefineCapsuleFunction" -> "compArgumentConditions"
    "compDefineCapsuleFunction" -> "compOrCroak"
    "compDefineCapsuleFunction" -> "compileCases"
    "compDefineCategory" -> "compDefineCategory1"
    "compDefineCategory" -> "compDefineLisplib"
    "compDefineCategory1" -> "compDefine1"
```

```

"compDefineCategory1" -> "compDefineCategory2"
"compDefineCategory2" -> "compMakeDeclaration"
"compDefineCategory2" -> "compOrCroak"
"compDefineCategory2" -> "compile"
"compDefineFunctor" -> "compDefineFunctor1"
"compDefineFunctor" -> "compDefineLispLib"
"compDefineFunctor1" -> "compMakeDeclaration"
"compDefineFunctor1" -> "compFunctorBody"
"compDefineFunctor1" -> "compile"
"compDefineLispLib" -> "compileDocumentation"
"compileCases" -> "compile"

}

```

A Category is represented by a DEF form with 4 parts:

- a name
- a distnature
- an SC
- a body

For example, the `BasicType` category is written as

```

BasicType(): Category == with
    "=": (%,%) -> Boolean    ++ x=y tests if x and y are equal.
    "~=": (%,%) -> Boolean   ++ x~y tests if x and y are not equal.

```

```
add
_~=(x:%,y:%) : Boolean == not(x=y)
```

Which compiles to the DEF form:

```
(DEF
  (|BasicType|)
  ((|Category|))
  (NIL)
  (\add|
    (CATEGORY |domain|
      (SIGNATURE  = (((|Boolean|) $ $)))
      (SIGNATURE ~= (((|Boolean|) $ $))))
    (CAPSULE
      (DEF
        (~= |x| |y|)
        (((|Boolean|) $ $)
         (NIL NIL NIL)
         (IF (= |x| |y|) |false| |true|)))))
```

### 5.1.1 defplist compDefine plist

We set up the `compDefine` function to handle the DEF keyword by setting the `special` keyword on the DEF symbol property list.

— postvars —

```
(eval-when (eval load)
  (setf (get 'def 'special) '|compDefine|))
```

---

### 5.1.2 defun compDefine

The `compDefine` function expects three arguments:

1. the `form` which is an def specifying the domain to define.
2. the `mode` a —Join—, which is a set of categories and domains
3. the `env` which is a list of functions and their modemap

```
[compDefine1 p141]
[$tripleCache p??]
[$tripleHits p??]
[$macroIfTrue p??]
[$packagesUsed p??]
```

— defun compDefine —

```
(defun |compDefine| (form mode env)
  (let (|$tripleCache| |$tripleHits| |$macroIfTrue| |$packagesUsed|)
    (declare (special |$tripleCache| |$tripleHits| |$macroIfTrue|
                  |$packagesUsed|))
    (setq |$tripleCache| nil)
    (setq |$tripleHits| 0)
    (setq |$macroIfTrue| nil)
    (setq |$packagesUsed| nil)
    (|compDefine1| form mode env)))
```

---

---

### 5.1.19 defvar \$NoValueMode

— initvars —

```
(defvar |$NoValueMode| '|NoValueMode|)
```

---

### 5.1.20 defvar \$EmptyMode

`$EmptyMode` is a constant whose value is `$EmptyMode`. It is used by `isPartialMode` to decide if a modemap is partially constructed. If the `$EmptyMode` constant occurs anywhere in the modemap structure at any depth then the modemap is still incomplete. To find this constant the `isPartialMode` function calls `CONTAINED $EmptyMode Y` which will walk the structure `Y` looking for this constant.

This transforms the operationAlist which is written out onto LISPLIBs. The original form of this list is a list of items of the form:

```
((<op> <signature>) (<condition> (ELT $ n)))
```

The new form is an op-Alist which has entries

```
(<op> . signature-Alist)
```

where signature-Alist has entries

```
(<signature> . item)
```

where item has form

```
(<slotNumber> <condition> <kind>)
```

```

  ((null (cdr z)) (list (car z) (list |$true| (list '|CondError|))))
  (t (cons (car z) (|optCONDtail| (cdr z)))))))
```

---

### 5.2.5 defvar \$BasicPredicates

If these predicates are found in an expression the code optimizer routine optPredicateIfTrue then optXLAM will replace the call with the argument. This is used for predicates that test the type of their argument so that, for instance, a call to integerp on an integer will be replaced by that integer if it is true. This represents a simple kind of compile-time type evaluation.

— initvars —

```
(defvar |$BasicPredicates| '(integerp stringp floatp))
```

---

### 5.2.6 defun optPredicateIfTrue

    ((or (compiled-function-p u) (mbpip u)) (bpiname u))
    (t nil)))
```

—————

### 5.2.9 Special case optimizers

Optimization functions are called through the OPTIMIZE property on the symbol property list. The current list is:

call	optCall
seq	optSEQ
eq	optEQ
minus	optMINUS
qsminus	optQSMINUS

```

-          opt-
lessp      optLESSP
spadcall   optSPADCALL
|          optSuchthat
catch      optCatch
cond       optCond
|mkRecord| optMkRecord
recordelt  optRECORDELT
setrecordelt optSETRECORDELT
recordcopy optRECORDCOPY

```

Be aware that there are case-sensitivity issues. When found in the s-expression, each symbol in the left column will call a custom optimization routine in the right column. The optimization routines are below. Note that each routine has a special chunk in postvars using eval-when to set the property list at load time.

These optimizations are done destructively. That is, they modify the function in-place using rplac.

Not all of the optimization routines are called through the property list. Some are called only from other optimization routines, e.g. optPackageCall.

### 5.2.10 defplist optCall

### 5.5 Indirect called comp routines

In the **compExpression** function there is the code:

```
(if (and (atom (car x)) (setq fn (getl (car x) 'special)))
  (funcall fn x m e)
  (|compForm| x m e))))
```

### 5.5.1 defplist compAdd plist

We set up the `compAdd` function to handle the `add` keyword by setting the `special` keyword on the `add` symbol property list.

— postvars —

```
(eval-when (eval load)
  (setf (get '|add| 'special) 'compAdd))
```

---

### 5.5.2 defun compAdd

The `compAdd` function expects three arguments:

1. the **form** which is an —add— specifying the domain to extend and a set of functions to be added
2. the **mode** a —Join—, which is a set of categories and domains
3. the **env** which is a list of functions and their modemap

The bulk of the work is performed by a call to `compOrCroak` which compiles the functions in the add form capsule.

The `compAdd` function returns a triple, the result of a call to `compCapsule`.

1. the **compiled capsule** which is a progn form which returns the domain
2. the **mode** from the input argument
3. the **env** prepended with the signatures of the functions in the body of the add.

### 5.5.8 defun compCapsuleItems

The variable data appears to be unbound at runtime. Optimized code won't check for this but interpreted code fails. We should PROVE that data is unbound at runtime but have not done so yet. Rather than remove the code entirely (since there MIGHT be a path where it is used) we check for the runtime bound case and assign \$myFunctorBody if data has a value.

The compCapsuleInner function in this file LOOKS like it sets data and expects code to manipulate the assigned data structure. Since we can't be sure we take the least disruptive course of action.

### 5.5.13 defplist compCase plist

We set up the `compCase` function to handle the `case` keyword by setting the `special` keyword on the `case` symbol property list.

— postvars —

```
(eval-when (eval load)
  (setf (get '|case| 'special) '|compCase|))
```

---

### 5.5.14 defun compCase

Will the jerk who commented out these two functions please NOT do so again. These functions ARE needed, and case can NOT be done by modemap alone. The reason is that A case B requires to take A evaluated, but B unevaluated. Therefore a special function is required. You may have thought that you had tested this on “failed” etc., but “failed” evaluates to it’s own mode. Try it on x case \$ next time.

An angry JHD - August 15th., 1984 [addDomain p248]

## 5.6 Functions for coercion

### 5.6.1 defun coerce

The function coerce is used by the old compiler for coercions. The function coerceInteractive is used by the interpreter. One should always call the correct function, since the representation of basic objects may not be the same. [keyedSystemError p??]

## 6.2 Indirect called postparse routines

In the **postTran** function there is the code:

```
((and (atom op) (setq f (getl op '|postTran|)))
  (funcall f x))
```

The functions in this section are called through the symbol-plist of the symbol being parsed.  
The original list read:

add	postAdd
@	postAtSign
:BF:	postBigFloat
Block	postBlock
CATEGORY	postCategory
COLLECT	postCollect

```

:           postColon
::          postColonColon
,
postComma
construct  postConstruct
==         postDef
=>        postExit
if          postIf
in          postIn      ;" the infix operator version of in"
IN          postIn      ;" the iterator form of in"
Join        postJoin
->        postMapping
==>       postMDef
pretend    postPretend
QUOTE      postQUOTE
Reduce     postReduce
REPEAT     postRepeat
Scripts    postScripts
;           postSemiColon
Signature  postSignature
/           postSlash
@Tuple     postTuple
TupleCollect  postTupleCollect
where      postWhere
with       postWith

```

## PARSE forms

### 8.1 The original meta specification

This package provides routines to support the Metalanguage translator writing system. Metalanguage is described in META/LISP, R.D. Jenks, Tech Report, IBM T.J. Watson Research Center, 1969. Familiarity with this document is assumed.

Note that META/LISP and the meta parser/generator were removed from Axiom. This information is only for documentation purposes.

```
%      Scratchpad II Boot Language Grammar, Common Lisp Version
%      IBM Thomas J. Watson Research Center
%      Summer, 1986
%
%      NOTE: Substantially different from VM/LISP version, due to
%             different parser and attempt to render more within META proper.

### 8.2.68 The PARSE implicit routines

These symbols are not explicitly referenced in the source. Nevertheless, they are called during runtime. For example, PARSE-SemiColon is called in the chain:

```

PARSE-Enclosure {loc0=nil,loc1="(V ==> Vector; "}
PARSE-Expr
PARSE-LedPart
PARSE-Operation
PARSE-getSemanticForm
PARSE-SemiColon

```

so there is a bit of indirection involved in the call.

## 8.3 The PARSE support routines

This section is broken up into 3 levels:

- String grabbing: Match String, Match Advance String
- Token handling: Current Token, Next Token, Advance Token
- Character handling: Current Char, Next Char, Advance Char
- Line handling: Next Line, Print Next Line
- Error Handling
- Floating Point Support
- Dollar Translation

### 8.3.1 String grabbing

String grabbing is the art of matching initial segments of the current line, and removing them from the line before the get tokenized if they match (or removing the corresponding current tokens).

### 8.3.2 defun match-string

The match-string function returns length of X if X matches initial segment of inputstream.

[unget-tokens p458]  
 [skip-blanks p454]  
 [line-past-end-p p635]  
 [current-char p463]  
 [initial-substring-p p456]  
 [subseq p??]  
 [\$line p633]  
 [line p633]

— defun match-string —

```
(defun match-string (x)
  (unget-tokens) ; So we don't get out of synch with token stream
  (skip-blanks)
  (if (and (not (line-past-end-p current-line)) (current-char))
    (initial-substring-p x)
    (subseq (line-buffer current-line) (line-current-index current-line)))))
```

---

### 8.3.3 defun skip-blanks

[current-char p463]  
 [token-lookahead-type p455]  
 [advance-char p??]

— defun skip-blanks —

```
(defun skip-blanks ()
  (loop (let ((cc (current-char)))
    (if (not cc) (return nil))
    (if (eq (token-lookahead-type cc) 'white)
      (if (not (advance-char)) (return nil))
      (return t))))
```

---

— initvars —

```
(defvar Escape-Character #\\ "Superquoting character.")
```

---

### 8.3.4 defun token-lookahead-type

[Escape-Character p??]

— defun token-lookahead-type —

```
(defun token-lookahead-type (char)
  "Predicts the kind of token to follow, based on the given initial character."
  (declare (special Escape-Character))
  (cond
    ((not char) 'eof)
    ((or (char= char Escape-Character) (alpha-char-p char)) 'id)
    ((digitp char) 'num)
    ((char= char #\') 'string)
    ((char= char #\[) 'bstring)
    ((member char '#\Space #\Tab #\Return) :test #'char=) 'white)
    (t 'special-char)))
```

---

### 8.3.5 defun match-advance-string

The match-string function returns length of X if X matches initial segment of inputstream. If it is successful, advance inputstream past X. [quote-if-string p456]

[current-token p461]  
 [match-string p454]

 [meta-error-handler p464]

— defun meta-syntax-error —

```
(defun meta-syntax-error (&optional (wanted nil) (parsing nil))
  (declare (special meta-error-handler))
  (funcall meta-error-handler wanted parsing))
```

— — —

### 8.3.33 Floating Point Support

#### 8.3.34 defun floatexpid

**TPDHERE:** The use of and in spadreduce is undefined. rewrite this to loop

[floatexpid identp (vol5)]  
 [floatexpid pname (vol5)]  
 [spadreduce p??]  
 [collect p379]  
 [step p??]  
 [maxindex p??]  
 [floatexpid digitp (vol5)]

— defun floatexpid —

```
(defun floatexpid (x &aux s)
  (when (and (identp x) (char= (char-upcase (elt (setq s (pname x)) 0)) #\E)
             (> (length s) 1)
             (spadreduce and 0 (collect (step i 1 1 (maxindex s))
                                         (digitp (elt s i))))))
    (read-from-string s t nil :start 1)))
```

— — —

### 8.3.35 Dollar Translation

#### 8.3.36 defun dollarTran

[\$InteractiveMode p??]

— defun dollarTran —

```
(defun |dollarTran| (dom rand)
  (let ((eltWord (if |$InteractiveMode| '|$elt| '|elt|)))
    (declare (special |$InteractiveMode|))
    (if (and (not (atom rand)) (cdr rand))
        (cons (list eltWord dom (car rand)) (cdr rand))
        (list eltWord dom rand))))
```

---

### 8.3.37 Applying metagrammatical elements of a production (e.g., Star).

- **must** means that if it is not present in the token stream, it is a syntax error.
- **optional** means that if it is present in the token stream, that is a good thing, otherwise don't worry (like [ foo ] in BNF notation).
- **action** is something we do as a consequence of successful parsing; it is inserted at the end of the conjunction of requirements for a successful parse, and so should return T.
- **sequence** consists of a head, which if recognized implies that the tail must follow. Following tail are actions, which are performed upon recognizing the head and tail.

### 8.3.38 defmacro Bang

If the execution of prod does not result in an increase in the size of the stack, then stack a NIL. Return the value of prod.

— defmacro bang —

```
(defmacro bang (lab prod)
  '(progn
    (setf (stack-updated reduce-stack) nil)
    (let* ((prodvalue ,prod) (updated (stack-updated reduce-stack)))
      (unless updated (push-reduction ',lab nil))
      prodvalue)))
```

---

### 8.3.39 defmacro must

[meta-syntax-error p465]

— defmacro must —

```
(defmacro must (dothis &optional (this-is nil) (in-rule nil))
  '(or ,dothis (meta-syntax-error ,this-is ,in-rule)))
```

---

### 8.3.40 defun action

— defun action —

```
(defun action (dothis) (or dothis t))
```

---

### 8.3.41 defun optional

— defun optional —

```
(defun optional (dothis) (or dothis t))
```

---

### 8.3.42 defmacro star

Succeeds if there are one or more of PROD, stacking as one unit the sub-reductions of PROD and labelling them with LAB. E.G., (Star IDs (parse-id)) with A B C will stack (3 IDs (A B C)), where (parse-id) would stack (1 ID (A)) when applied once. [stack-size p??]  
 [push-reduction p468]  
 [pop-stack-1 p550]

— defmacro star —

```
(defmacro star (lab prod)
  '(prog ((oldstacksize (stack-size reduce-stack)))
    (if (not ,prod) (return nil))
  loop
    (if (not ,prod)
      (let* ((newstacksize (stack-size reduce-stack))
             (number-of-new-reductions (- newstacksize oldstacksize)))
        (if (> number-of-new-reductions 0)
          (return (do ((i 0 (1+ i)) (accum nil))
```

```
((= i number-of-new-reductions)
  (push-reduction ',lab accum)
  (return t))
  (push (pop-stack-1) accum)))
  (return t)))
(go loop)))
```

---

### 8.3.43 Stacking and retrieving reductions of rules.

#### 8.3.44 defvar \$reduce-stack

Stack of results of reduced productions. [\$stack p92]

— initvars —

```
(defvar reduce-stack (make-stack) )
```

---

#### 8.3.45 defmacro reduce-stack-clear

— defmacro reduce-stack-clear —

```
(defmacro reduce-stack-clear () '(stack-load nil reduce-stack))
```

---

#### 8.3.46 defun push-reduction

## The Compiler

### 14.0.58 defvar \$newConlist

A list of new constructors discovered during compile. These are used in a call to `extendLocalLibdb` when a user compiles new local code.

— initvars —

```
(defvar |$newConlist| nil
  "A list of new constructors discovered during compile")
```

---

### 14.1 Compiling EQ.spad

Given the top level command:

```
)co EQ
```

The default call chain looks like:

```
1> (|compiler| ...)
2> (|compileSpad2Cmd| ...)
  Compiling AXIOM source code from file /tmp/A.spad using old system
  compiler.
3> (|compilerDoit| ...)
4> (|RQ,LIB|)
5> (RF-1 ...)
6> (SPAD ...)
AXSERV abbreviates package AxiomServer
7> (S-PROCESS ...)
```

```

8> (|compTopLevel| ...)
9> (|compOrCroak| ...)
10> (|compOrCroak1| ...)
11> (|comp| ...)
12> (|compNoStacking| ...)
13> (|comp2| ...)
14> (|comp3| ...)
15> (|compExpression| ...)
*
16> (|compWhere| ...)
17> (|comp| ...)
18> (|compNoStacking| ...)
19> (|comp2| ...)
20> (|comp3| ...)
21> (|compExpression| ...)

```

In order to explain the compiler we will walk through the compilation of EQ.spad, which handles equations as mathematical objects. We start the system. Most of the structure in Axiom are circular so we have to the `*print-circle*` to true.

```

root@spiff:/tmp# axiom -nox

(1) -> )lisp (setq *print-circle* t)

Value = T

```

We trace the function we find interesting:

```

(1) -> )lisp (trace |compiler|)

Value = (|compiler|)

```

## 14.2 The top level compiler command

This is the graph of the functions used for compDefine. The syntax is a graphviz dot file. To generate this graph as a JPEG file, type:

```

tangle v9compDefine.dot bookvol9.pamphlet >v9compdefine.dot
dot -Tjpg v9compiler.dot >v9compiler.jpg

```

— v9compiler.dot —

```

### 14.2.1 defun compiler

We compile the spad file. We can see that the `compiler` function gets a list

```
(1) -> )co EQ
1> (|compiler| (EQ))
```

In order to find this file, the `pathname` and `pathnameType` functions are used to find the location and pathname to the file. They `pathnameType` function eventually returns the fact that this is a spad source file. Once that is known we call the `compileSpad2Cmd` function with a list containing the full pathname as a string.

```
1> (|compiler| (EQ))
2> (|pathname| (EQ))
<2 (|pathname| #p"EQ")
```

```

2> (|pathnameType| #p"EQ")
   3> (|pathname| #p"EQ")
   <3 (|pathname| #p"EQ")
<2 (|pathnameType| NIL)
2> (|pathnameType| "/tmp/EQ.spad")
   3> (|pathname| "/tmp/EQ.spad")
   <3 (|pathname| #p"/tmp/EQ.spad")
<2 (|pathnameType| "spad")
2> (|pathnameType| "/tmp/EQ.spad")
   3> (|pathname| "/tmp/EQ.spad")
   <3 (|pathname| #p"/tmp/EQ.spad")
<2 (|pathnameType| "spad")
2> (|pathnameType| "/tmp/EQ.spad")
   3> (|pathname| "/tmp/EQ.spad")
   <3 (|pathname| #p"/tmp/EQ.spad")
<2 (|pathnameType| "spad")
2> (|compileSpad2Cmd| ("/tmp/EQ.spad"))

### 14.2.2 defun compileSpad2Cmd

The argument to this function, as noted above, is a list containing the string pathname to the file.

```
2> (|compileSpad2Cmd| ("tmp/EQ.spad"))
```

There is a fair bit of redundant work to find the full filename and pathname of the file. This needs to be eliminated.

The trace of the functions in this routines is:

```
1> (|selectOptionLC| "compiler" (|abbreviations| |boot| |browse| |cd| |clear| |close| |compiler| |copy|
<1 (|selectOptionLC| |compiler|)
1> (|selectOptionLC| |compiler| (|abbreviations| |boot| |browse| |cd| |clear| |close| |compiler| |copy|
<1 (|selectOptionLC| |compiler|)
1> (|pathname| (EQ))
<1 (|pathname| #p"EQ")
1> (|pathnameType| #p"EQ")
2> (|pathname| #p"EQ")
<2 (|pathname| #p"EQ")
<1 (|pathnameType| NIL)
1> (|pathnameType| "/tmp/EQ.spad")
2> (|pathname| "/tmp/EQ.spad")
<2 (|pathname| #p"/tmp/EQ.spad")
<1 (|pathnameType| "spad")
1> (|pathnameType| "/tmp/EQ.spad")
2> (|pathname| "/tmp/EQ.spad")
<2 (|pathname| #p"/tmp/EQ.spad")
<1 (|pathnameType| "spad")
1> (|pathnameType| "/tmp/EQ.spad")
2> (|pathname| "/tmp/EQ.spad")
<2 (|pathname| #p"/tmp/EQ.spad")
<1 (|pathnameType| "spad")
1> (|compileSpad2Cmd| ("/tmp/EQ.spad"))
2> (|pathname| ("/tmp/EQ.spad"))
<2 (|pathname| #p"/tmp/EQ.spad")
2> (|pathnameType| #p"/tmp/EQ.spad")
3> (|pathname| #p"/tmp/EQ.spad")
<3 (|pathname| #p"/tmp/EQ.spad")
<2 (|pathnameType| "spad")
2> (|updateSourceFiles| #p"/tmp/EQ.spad")
3> (|pathname| #p"/tmp/EQ.spad")
<3 (|pathname| #p"/tmp/EQ.spad")
3> (|pathname| #p"/tmp/EQ.spad")
<3 (|pathname| #p"/tmp/EQ.spad")
3> (|pathnameType| #p"/tmp/EQ.spad")
4> (|pathname| #p"/tmp/EQ.spad")
<4 (|pathname| #p"/tmp/EQ.spad")
<3 (|pathnameType| "spad")
```

```

3> (|pathname| ("EQ" "spad" "*"))
<3 (|pathname| #p"EQ.spad")
3> (|pathnameType| #p"EQ.spad")
  4> (|pathname| #p"EQ.spad")
    <4 (|pathname| #p"EQ.spad")
      <3 (|pathnameType| "spad")
<2 (|updateSourceFiles| #p"EQ.spad")
2> (|namestring| ("/tmp/EQ.spad"))
  3> (|pathname| ("/tmp/EQ.spad"))
    <3 (|pathname| #p"/tmp/EQ.spad")
<2 (|namestring| "/tmp/EQ.spad")
Compiling AXIOM source code from file /tmp/EQ.spad using old system
compiler.

```

Again we find a lot of redundant work. We finally end up calling **compilerDoit** with a constructed argument list:

```

2> (|compilerDoit| NIL (|rq| |lib|))

          (|sayBrightly| (">>> Warning " |%b| ,x |%d| " was not found"))))))))
```

---

#### 14.2.6 defun /rq

Compile with quiet output [/rf-1 p572]  
[echo-meta p??]

— defun /rq —

```
(defun /rq (&rest foo &aux (echo-meta nil))
  (declare (special Echo-Meta) (ignore foo))
  (/rf-1 nil))
```

---

#### 14.2.7 defun /rf

Compile with noisy output [/rf-1 p572]  
[echo-meta p??]

— defun /rf —

```
(defun /rf (&rest foo &aux (echo-meta t))
  (declare (special echo-meta) (ignore foo))
  (/rf-1 nil))
```

---

### 14.2.8 defun /RQ,LIB

This function simply calls /rf-1.

```
(2) -> )co EQ
      Compiling AXIOM source code from file /tmp/EQ.spad using old system
      compiler.
1> (|compilerDoit| NIL (|rq| |lib|))
2> (|/RQ,LIB|)
3> (/RF-1 NIL)
...[snip]...
<3 (/RF-1 T)
<2 (|/RQ,LIB| T)
<1 (|compilerDoit| T)

[/rf-1 p572]
[|RQ,LIB echo-meta (vol5)]
[$lisplib p??]

— defun /RQ,LIB —

(defun |/RQ,LIB| (&rest foo &aux (echo-meta nil) ($lisplib t))
  (declare (special echo-meta $lisplib) (ignore foo))
  (/rf-1 nil))
```

---

### 14.2.9 defun /rf-1

Since this function is called with nil we fall directly into the call to the function **spad**:

```
(2) -> )co EQ
      Compiling AXIOM source code from file /tmp/EQ.spad using old system
      compiler.
1> (|compilerDoit| NIL (|rq| |lib|))
2> (|/RQ,LIB|)
3> (/RF-1 NIL)
4> (SPAD "/tmp/EQ.spad")
...[snip]...
<4 (SPAD T)
<3 (/RF-1 T)
<2 (|/RQ,LIB| T)
<1 (|compilerDoit| T)

[/rf-1 makeInputFilename (vol5)]
[ncINTERPFILE p627]
calls/rf-1spad [/editfile p??]
```

[echo-meta p??]

— defun /rf-1 —

```
(defun /rf-1 (ignore)
  (declare (ignore ignore))
  (let* ((input-file (makeInputFilename /editfile))
         (type (pathname-type input-file)))
    (declare (special echo-meta /editfile))
    (cond
      ((string= type "lisp") (load input-file))
      ((string= type "input") (|ncINTERPFILE| input-file echo-meta))
      (t (spad input-file))))
```

---

### 14.2.10 defun spad

Here we begin the actual compilation process.

```
1> (SPAD "/tmp/EQ.spad")
2> (|makeInitialModemapFrame|)
<2 (|makeInitialModemapFrame| ((NIL)))
2> (INIT-BOOT/SPAD-READER)
<2 (INIT-BOOT/SPAD-READER NIL)
2> (OPEN "/tmp/EQ.spad" :DIRECTION :INPUT)

<1 (OPEN #<output stream "libdb.text">)

```

The major steps in this process involve the **preparse** function. (See book volume 5 for more details). The **preparse** function returns a list of pairs of the form: ( (linenumber . linestring) .... (linenumber . linestring)) For instance, for the file EQ.spad, we get:

```

<2 (PREPARSE (
(19 . "Equation(S: Type): public == private where")
(20 . " (Ex ==> OutputForm;")
(21 . " public ==> Type with")
(22 . " (\\"=\\": (S, S) -> $;")
...[skip]...
(202 . "           inv eq == [inv lhs eq, inv rhs eq]);")
(203 . "     if S has ExpressionSpace then")
(204 . "           subst(eq1,eq2) ==")
(205 . "             (eq3 := eq2 pretend Equation S;")
(206 . "               [subst(lhs eq1,eq3),subst(rhs eq1,eq3)]))))"))

```

      (compile name))
    (when (or |$PrettyPrint| (not (is-console st)))
      (print-full body st) (force-output st))))
```

—————

### 14.2.14 defun def-rename

```
[def-rename p587]
```

— defun def-rename —

```
(defun def-rename (x)
  (cond
    ((symbolp x)
     (let ((y (get x 'rename))) (if y (first y) x)))
    ((and (listp x) x)
     (if (eqcar x 'quote)
         x
         (cons (def-rename (first x)) (def-rename (cdr x)))))
    (x)))
```

—————

Given:

```
CohenCategory(): Category == SetCategory with
  kind:(CExpr)->Boolean
  operand:(CExpr, Integer)->CExpr
  numberOfOperand:(CExpr)->Integer
```

```
construct:(CExpr,CExpr)->CExpr
```

the resulting call looks like:

```
(|compOrCroak|
  (DEF (|CohenCategory|)
    ((|Category|))
    (NIL)
    (|Join|
      (|SetCategory|)
      (CATEGORY |package|
        (SIGNATURE |kind| ((|Boolean|) |CExpr|))
        (SIGNATURE |operand| (|CExpr| |CExpr| (|Integer|)))
        (SIGNATURE |numberOfOperand| ((|Integer|) |CExpr|))
        (SIGNATURE |construct| (|CExpr| |CExpr| |CExpr|))))
    |$EmptyMode|
    ((((
      (|$DomainsInScope|
        (FLUID . |true|)
        (special |$EmptyMode| |$NoValueMode|)))))))
```

This compiler call expects the first argument *x* to be a DEF form to compile, The second argument, *m*, is the mode. The third argument, *e*, is the environment.

#### 14.2.15 defun compOrCroak

[compOrCroak1 p589]

— defun compOrCroak —

```
(defun |compOrCroak| (form mode env)
  (|compOrCroak1| form mode env nil nil))
```

---

This results in a call to the inner function with

```
(|compOrCroak1|
  (DEF (|CohenCategory|)
    ((|Category|))
    (NIL)
    (|Join|
      (|SetCategory|)
      (CATEGORY |package|
        (SIGNATURE |kind| ((|Boolean|) |CExpr|))
        (SIGNATURE |operand| (|CExpr| |CExpr| (|Integer|))))
```

```

(SIGNATURE |numberOfOperand| ((|Integer|) |CExpr|))
(SIGNATURE |construct| (|CExpr| |CExpr| |CExpr|)))
|$EmptyMode|
(((
  |$DomainsInScope|
  (FLUID . |true|)
  (special |$EmptyMode| |$NoValueMode|))))
NIL
NIL
|comp|)

```

The inner function augments the environment with information from the compiler stack `$compStack` and `$compErrorMessageStack`. Note that these variables are passed in the argument list so they get preserved on the call stack. The calling function gets called for every inner form so we use this implicit stacking to retain the information.

# Chapter 16

## Level 0

### 16.1 Line Handling

#### 16.1.1 Line Buffer

The philosophy of lines is that

- NEXT LINE will always return a non-blank line or fail.
- Every line is terminated by a blank character.

Hence there is always a current character, because there is never a non-blank line, and there is always a separator character between tokens on separate lines. Also, when a line is read, the character pointer is always positioned ON the first character.

#### 16.1.2 defstruct \$line

— initvars —

```
(defstruct line "Line of input file to parse."
  (buffer (make-string 0) :type string)
  (current-char #\Return :type character)
  (current-index 1 :type fixnum)
  (last-index 0 :type fixnum)
  (number 0 :type fixnum))
```

---

### 16.1.3 defvar \$current-line

The current input line.

— initvars —

```
(defvar current-line (make-line))
```

—————

### 16.1.4 defmacro line-clear

[\$line p633]
